HAL is a multi-disciplinary open access archive for the deposit and dissemination of scientific research documents, whether they are published or not. The documents may come from teaching and research institutions in France or abroad, or from public or private research centers.

L’archive ouverte pluridisciplinaire HAL, est destinée au dépôt et à la diffusion de documents scientifiques de niveau recherche, publiés ou non, émanant des établissements d’enseignement et de recherche français ou étrangers, des laboratoires publics ou privés.

Keywords: Maar, paleolimnology, hazards

Lake records provide insight into the interactions between human societies, past climate and the natural environment. Maar lake basin fills are key sites for paleoenvironmental studies covering the Holocene and periods beyond (Negendank and Zolitschka, 1993, Augustinus et al., 2012). They also could record sedimentary events linked to natural hazards specific to volcanic area such as crater outburst and limnic eruption (Anzidei et al., 2008, Chapron et al., 2010). Lake Pavin (French Massif Central, France) located in Western Europe is a meromictic maar formed ca. 7,000 years ago (Gewelt and Juvigné, 1988, Chapron et al., 2010). This lake is almost circular with an area of 44 ha and a maximum depth of 92 meters with anoxic waters below 60 meters depth. Recent studies on the water column confirm the presence of methane and carbon dioxide in these anoxic waters (Fig. 1, Busigny et al., 2014 and references therein).

Up to now, few paleoenvironmental studies have been made in this lake (Steibich et al., 2005, Schettler et al., 2007). Moreover, questions remain about the evolution of limnic and trophic status of this meromictic maar lake and natural hazards associated to it. For these reasons, this study focused on sedimentary deposits using geophysical mapping techniques (multibeam bathymetry and high-resolution seismic reflection) and sediment cores retrieved both in shallow water environments and within anoxic waters in the deep central basin (Fig. 1).

Multi-proxies analyses were carried out on sediments including X-Ray fluorescence, spectrophotometry and organic geochemistry by Rock-Eval pyrolysis. Radiocarbon dating has been performed both on leaves debris and bulk sediment in order to establish the chronology of sedimentary deposits (Blaauw, 2010).

Results report gas-rich sediments consisting primarily of diatoms, deposited in three sedimentary environments: a littoral area, a plateau clipped by a landslide scar in the northern part of the lake and a flat central basin surrounded by steep slopes (Chapron et al., 2010, 2012).

Fig. 1 – Geomorphological and bathymetric map of Lake Pavin and its catchment

In the central basin (Fig. 1), a 14 m long piston core was retrieved, covering the last 7,000 years. The sediment is composed of volcano-clastic materials covered by in-situ diatom-made sediment, interrupted by a massive unit resulting from a MWD. This event has been dated to ca. AD 1300 and corresponds to a fresh slide scar identified at the edge of the plateau (Chapron et al., 2010, 2012).
Throughout this core, changes in mineral and organic content reflect evolution in the trophic status of the lake from its origin to the present day, with a gradual transition from a young lacustrine system fed by clastic material toward an organic-rich maar with strong algal supplies. Results also show major differences in organic and inorganic content once the MWD occurred, highlighting its impact on the limnological evolution.

On the plateau (Fig. 1), acoustic mapping and sedimentary analyses indicate a MWD deposit surrounded by diatomites. This MWD is dated around AD 600 and may have been caused by a crater outburst that was followed by a water-level drop in the lake and a catastrophic flood in the valley downstream.

On the littoral environment, which consist of brownish sediments (Fig. 1), two erosive layers made of sand and/or leaves have been correlated to previously mentioned events (AD 600 and AD 1300) and have been deposited after wave-induced erosion of the lake shores. The major lake-level drop is also confirmed by (1) sedimentological evidences for a crater outburst flood downstream in the valley and (2) shifts in sedimentary organic matter composition after AD 600 within the entire lake.

Finally, this study underlines the impact of MWD on limnology. Even if the triggers of these major events remain unclear at this date, this work underlines their key-role on the trophic status evolution of maar Lake Pavin during the late Holocene. It also illustrates the instability of such gas-rich sediments, which can be easily reworked under climatic and tectonic trigger. Because catastrophic phenomena such as limnic eruption can occur into meromictic maar lakes, further evaluations have to be made to define the role of gravitational processes on natural hazards linked to these peculiar environments.
